

Assignment 1

AIGC 5002

- (1) Split the dataset to 80-20 for training and test respectively. The dataset contains missing value.
- (2) Apply the Logistic Regression method on the dataset and perform a classification. Report the performance of the classifier with all classification metrics, including the confusion matrix.
- (3) Apply the k-mean clustering method on the dataset after the class labels are excluded, and perform clustering with two groups ($k=2$). Next, add/assign the clustering labels to the dataset. Report all classification metrics, including the confusion matrix.
- (4) Explore the optimum k value with the dataset used in Section 3 using the elbow method and plot the results.
- (5) Submit a notebook file (ipynb) that contains all source codes and the aforementioned results.
