

Use tensorflow.keras APIs to construct and train an MLP with minimum two hidden layers to predict the variable 'Training Hours Provided' using all other features in the dataset.

- 1- Split the dataset to **70%, 30%** for training and validation respectively.
- 2- Use **mean_squared_error** loss function.
- 3- Use **model.summary()** to display the summary of the neural network's layers and parameters.
- 4- The number of neurons for hidden layers and hyper-parameter values should be chosen in a way that to produce **the loss value of 0.05 or less for training data.**
- 5- Plot the **loss values of all epochs** for both training and validation data.
- 6- Plot the **predicted values vs the target values** for validation data.
- 7- Submit **an ipynb file** with all source codes and the aforementioned results.
